1. Project Overview

The Online Job Portal is a web application that connects employers who want to hire with job seekers who are looking for work. It has three kinds of users, and each one gets a separate dashboard with its own features: the **Admin** manages and moderates the platform, the **Employer** posts jobs and reviews applicants, and the **Job Seeker** searches for jobs and applies to them.

This document summarises the work completed so far by Team 9, the ideas and suggestions put forward for the project, and the other contributions made toward its completion.

2. Work Completed So Far

2.1 Requirement analysis

- Studied the project brief and identified the three user roles and the purpose of each dashboard.
- Listed the main features each role needs and separated the essential features from the optional ones.
- Defined the project scope so the work could be planned in clear, manageable stages.

2.2 Roadmap and planning

A step-by-step development roadmap was prepared, divided into eight phases:

Phase	Focus	Key outcomes
1	Planning and setup	Feature list, database design, project structure, Git repository
2	Authentication and roles	Register and login, JWT, password hashing, role-based access, protected routes

Phase	Focus	Key outcomes
3	Job Seeker module	Profile and resume, job search with filters, apply, track status, saved jobs
4	Employer module	Company profile, post/edit/delete jobs, view and shortlist applicants
5	Admin module	Manage users and employers, moderate jobs, dashboard statistics
6	Polish and extras	Responsive UI, validation, loading and error states, optional extras
7	Testing and deployment	End-to-end testing per role, bug fixes, hosting and production settings
8	Documentation	Project report, PPT presentation, README with setup steps

2.3 Front-end prototype

- Built a front-end prototype of the portal showing the dashboard and main screens for each of the three roles.
- Used the prototype to confirm the layout, navigation and user flow before adding backend logic.

2.4 Moving toward a deployable application

- Took the prototype forward toward a fully functional, deployment-ready application with a backend, a database and hosting.
- Planned the deployment setup: React front end on Vercel or Netlify, Node/Express back end on Render, and MongoDB Atlas for the database.

2.5 Project deliverables

- Planned the project report and the PPT presentation that form part of the final submission.

3. Ideas and Suggestions Contributed by the Team

The ideas below shaped how the portal is structured and what each role can do.

3.1 Role-based access control

Each user should see and reach only the pages that belong to their role. This is enforced both on the front end (protected routes) and on the back end (middleware that checks the user's role), so that a job seeker cannot open employer or admin pages even by typing the address directly.

3.2 Features proposed for each role

Role	Proposed features	Benefit
Job Seeker	Profile creation and resume upload; job search with filters for location, category, salary and job type; apply to jobs; track application status (applied, shortlisted, rejected); save jobs for later.	Makes it quick to find suitable jobs and to follow up on applications.
Employer	Company profile; post, edit and delete jobs; view applicants for each job; shortlist or reject candidates; status changes that the job seeker can see.	Lets employers manage hiring from one place.
Admin	Approve or block users and employers; moderate and remove inappropriate or fake job posts; dashboard with totals for users, jobs and applications.	Keeps the platform trustworthy and gives an overview of activity.

3.3 Data design

The database was planned around five collections so that the data stays organised and easy to query.

Collection	Purpose
Users	Stores account details, hashed passwords and the user's role
Companies	Employer company profiles linked to employer accounts
Jobs	Job postings with title, description, location, salary, type and the employer who posted them
Applications	Links a job seeker to a job and records the application status
Notifications	Messages about status changes and platform events

3.4 Optional improvements suggested

- Email notifications when an application status changes.
- Job alerts for job seekers based on their saved search preferences.
- Pagination on job listings so the pages stay fast as the number of jobs grows.
- Form validation and clear loading and error messages across the application.

3.5 Technology and deployment suggestions

Layer	Suggested choice	Reason
Front end	React	Component-based, well suited to separate dashboards
Back end	Node.js with Express	Simple REST API, same language as the front end
Database	MongoDB Atlas	Flexible documents and free cloud hosting
Authentication	JWT with password hashing	Stateless login with secure credential storage
Hosting	Vercel or Netlify, Render	Free tiers that are easy to deploy and update

4. Other Contributions

Area	Contribution
Planning	Scope definition, role and feature breakdown, and the phased roadmap.
Documentation	Project report, presentation slides, and a README explaining setup and the live link.
Testing	Checking the main flow of each role end to end (register, login, post or apply, review) and fixing the bugs found.
Deployment	Preparing environment variables, CORS settings and hosting so the application runs in production.

5. Approach and Tools

The project was planned and directed by the team and developed with the help of an AI assistant (Claude by Anthropic), which was used for the roadmap, the prototype and the build work. The team reviewed the output at each stage and decided which features and technologies to use.

6. Remaining Work and Next Steps

- Complete and test every role's full flow against the roadmap.
- Finish deployment and confirm the live link works for all three dashboards.
- Finalise the project report and the PPT presentation.
- Add the optional improvements (email notifications, job alerts, pagination) if time allows.

7. Conclusion

The project has moved from the brief to a clear plan, a working front-end prototype and a defined path to a deployed, fully functional portal. The ideas contributed, namely role-based access, role-specific features, a clean data design and a practical deployment plan, give the Online Job Portal a solid foundation that serves administrators, employers and job seekers.
